

THE CREDIT RATING INDUSTRY

RICHARD CANTOR AND FRANK PACKER

As financial market complexity and borrower diversity have grown over time, investors and regulators have increased their reliance on the opinions of the credit rating agencies. At the same time, the number of rating agencies operating in the United States and abroad has risen sharply. Together, these trends have prompted market participants and policymakers to assess the performance of the agencies and the adequacy of public oversight of the ratings industry.

This article provides background for such a reassessment by investigating the evolution and economics of the industry, the growth of ratings-dependent regulations, and the reliability and comparability of the agencies' ratings. We examine the correspondence of ratings with default rates and report differences among major agencies in their ratings for junk bonds, international banks, and mortgage-backed securities.

Our findings raise several questions about the current uses of ratings. While the agencies provide accurate rank-orderings of default risk, the meanings of specific ratings vary over time and across the agencies. Since these ratings are used as the basis of most investor guidelines and government regulations, the variations in meaning could have serious implications. In light of the possibilities for ratings misuse, the current reevaluation of ratings-dependent regulations and the adequacy of public oversight seems well justified.

I. THE EVOLUTION AND ECONOMICS OF THE RATINGS INDUSTRY

Rating Agency Origins, Owners, and Symbols

The precursors of bond rating agencies were the

RICHARD CANTOR is assistant vice president at The Federal Reserve Bank of New York.

FRANK PACKER is an economist at the Federal Reserve Bank of New York.

mercantile credit agencies, which rated merchants' ability to pay their financial obligations. In 1841, in the wake of the financial crisis of 1837, Louis Tappan established the first mercantile credit agency in New York. Robert Dun subsequently acquired the agency, which published its first ratings guide in 1859. A similar mercantile rating agency was formed in 1849 by John Bradstreet, who published a ratings book in 1857. In 1933, the two agencies were consolidated into Dun and Bradstreet, which became the owner of Moody's Investors Service in 1962.

The expansion of the ratings business to securities ratings began in 1909 when John Moody started to rate U.S. railroad bonds. A year later, Moody extended his ratings activity to utility and industrial bonds. Poor's Publishing Company issued its first ratings in 1916, Standard Statistics Company in 1922, and the Fitch Publishing Company in 1924. The number of bond rating agencies in the U.S. reverted to three when Standard Statistics and Poor's Publishing Company merged to form Standard & Poor's (S&P) in 1941.

The most significant new entry in the United States since that time has been the Chicago-based Duff & Phelps, which began to provide bond ratings for a wide range of companies in 1982, although it had researched public utility companies since 1932. Another major ratings provider — McCarthy, Crisanti, and Maffei — was founded in 1975 and acquired by Xerox Financial Services before its fixed-income rating and research service was merged into Duff & Phelps in 1991.

The four major rating agencies face competition from more specialized agencies. For example, Thomson Bankwatch and IBCA in the United States rate financial institutions exclusively, and A.M. Best rates insurance companies' claims-paying abilities.

Analysts employed by many financial institutions regularly make recommendations to buy or sell that implicitly confirm or contradict the agencies' ratings. To the extent that the analyses underlying these recommendations are made public, they provide alternative perspectives to the judgments of the rating agencies.

As capital flows in international financial markets have shifted from the banking sector to capital markets, credit ratings have also begun to make a mark overseas. Credit ratings are in use in the financial markets of most developed economies and several emerging market countries as well (see Dale and Thomas [1991]).

With demand rising in foreign countries, the number of foreign-based rating agencies has increased.

Along with the four largest U.S. raters, one other U.S., one British, two Canadian, and three Japanese firms are listed among the world's "most influential" rating agencies by the *Financial Times* in its publication, *Credit Ratings International*. The principal characteristics of all eleven agencies are reported in Exhibit 1.

The ownership structures of the U.S. rating agencies do not generally present serious conflict of interest problems.¹ The major agencies are all either independent or owned by non-financial companies, although two until recently were owned by financial companies. Moody's is a subsidiary of Dun and Bradstreet, which dominates the market for commercial credit ratings. Standard & Poor's is a subsidiary of McGraw-Hill, a major publishing company with a strong business information focus. Fitch, initially a publishing company, was bought by an independent investors group in 1989.

Duff & Phelps Credit Ratings is a subsidiary of Duff & Phelps, Inc., whose affiliates offer investment management, financial consulting, and investment research services. By late 1994, however, Duff & Phelps Credit Ratings is expected to become an independent company as its shares are spun off to the shareholders of Duff & Phelps, Inc., itself a closely held company. Thomson Bankwatch was a subsidiary of Keefe, Bruyette, and Woods, a brokerage firm, until March 1989, when it was sold to the Thomson Corporation, a large private international publishing conglomerate.

Most of the non-U.S. firms are also independent. The London-based rating agency, IBCA, is independently owned, as are the two Canadian rating agencies. Two of the rating agencies from Japan, however, are owned by consortiums of financial institutions, including some for which credit ratings are issued.

Over time, the agencies have expanded the depth and frequency of their coverage. The four leading U.S. credit rating agencies rate not only the long-term bonds issued by U.S. corporations, but also a wide variety of other debt instruments: municipal bonds, asset-backed securities, preferred stocks, medium-term note programs, shelf registrations, private placements, commercial paper programs, and bank certificates of deposit. More recently, ratings have been applied to other types of risks, including the counterparty risk posed by derivative products companies and other institutions, the claims-paying ability of insurance companies, the performance risk of mortgage servicers, and the price volatility of mutual funds and

mortgage-backed securities.

Increased foreign demand has also led to a dramatic overseas expansion of the established U.S. rating agencies. Over the past ten years, Moody's has opened offices in Tokyo, London, Paris, Sydney, Frankfurt, and Madrid, and now rates the securities of approximately 1,200 non-U.S. issuers (out of more than 4,500 total). Standard & Poor's has set up offices in Tokyo, London, Paris, Melbourne, Toronto, Frankfurt, Stockholm, and Mexico City, and has established affiliations or acquired local rating agencies in Sweden, Australia, Spain, and Mexico. Duff & Phelps has formed joint ventures in Mexico and several other Latin American countries. The established U.S. agencies appear to have a competitive advantage over their foreign counterparts in the business of providing independent, credible securities ratings.

The bond ratings assigned by all the rating agencies are meant to indicate the likelihood of default or delayed payment of the security. Most of the rating agencies have long had their own system of symbols — some using letters, others using numbers, many both — for ranking the risk of default from extremely safe to highly speculative. Gradually, however, a rough correspondence among the major agencies' ratings has emerged (Exhibit 2).²

To provide finer rating gradations to help investors distinguish more carefully among issuers, Fitch in 1973, Standard & Poor's in 1974, and Moody's in 1982 started attaching plus and minus symbols to their ratings. Other modifications of the grading schemes — including the addition of a "credit watch" category to denote that a rating is under review — have also become standard. In the remainder of this article,

the symbols currently employed by Standard & Poor's, Fitch, Duff & Phelps, and others are used to refer to the ratings of all agencies.

The Transition to Charging Issuers and the Role of Reputation

Agencies initially provided public ratings of an issuer free of charge, and financed their operations solely through the sale of publications and related materials. The publications, which are easily copied once published, however, did not yield sufficient returns to justify intensive coverage. As the demand on rating agencies for faster and more comprehensive service increased, agencies began to charge issuers for ratings. They then used these revenues to expand services and products and to compete with private-sector analysts at other financial institutions.

The default of Penn Central on \$82 million of commercial paper in 1970 was a catalyst in the transition to charging issuers. As the commercial paper market grew very rapidly in the 1960s, with little regard for credit quality, investors tended to assume that any firm with a household name was an acceptable credit risk. When Penn Central defaulted during the 1970 recession, however, investors began to question the financial condition of many companies and refused to roll over their commercial paper. Facing a liquidity crisis, many of these companies also defaulted.

To reassure nervous investors, issuers actively

sought credit ratings, and it became established market practice that new debt issues coming to market have at least one credit rating. With the demand for rating services rising, the agencies found they were able to impose charges on issuers.

Fitch and Moody's started to charge corporate issuers for ratings in 1970, and Standard & Poor's followed suit a few years later. (Standard & Poor's started to charge municipal bond issuers for ratings in 1968.) Now, according to one estimate, roughly four-fifths of Standard & Poor's revenue comes from issuer fees (Ederington and Yawitz [1987]).

Agencies charge fees that vary with the size and type of issue, but a representative fee on a new long-term corporate bond issue ranges from 2 to 3 basis points of the principal for each year the rating is maintained. Normally, the charge for any one bond issue has both a floor and a ceiling, and negotiated rates are available for frequent issuers. For issuers of commercial paper, Moody's and Standard & Poor's maintain quarterly charges based on amounts outstanding (up to 7 basis points) plus an annual fee.

While the current payment structure may appear to encourage agencies to assign higher ratings to satisfy issuers, the agencies also have an overriding incentive to maintain a reputation for high-quality, accurate ratings. If investors were to lose confidence in an agency's ratings, issuers would no longer believe they could lower their funding costs by obtaining its ratings.

EXHIBIT 2 ■ Long-Term Senior Debt Rating Symbols

Investment-Grade Ratings			Speculative-Grade Ratings		
S&P and others	Moody's	Interpretation	S&P and others	Moody's	Interpretation
AAA	Aaa	Highest quality	BB+	Ba1	Likely to fulfill obligations; ongoing uncertainty
AA+	Aa1	High quality	BB	Ba2	High-risk obligations
AA	Aa2		BB-	Ba3	
AA-	Aa3		B+	B1	
A+	A1	Strong payment capacity	B	B2	Current vulnerability to default, or in default (Moody's)
A	A2		B-	B3	
A-	A3		CCC+	Caa	
BBB+	Baa1	Adequate payment capacity	CCC	Ca	In bankruptcy or default, or other marked shortcoming
BBB	Baa2		C		
BBB-	Baa3		CCC-		

Notes: The other agencies listed in Exhibit 1 use the rating symbols of the first column, with the exception of DBRS (H and L symbols in place of + and -) and CBRS (H and L symbols in place of + and -, and + symbols that correspond to second and third letters). The agencies follow a variety of policies with respect to the number of ratings symbols given below B-.

As one industry observer puts it, "every time a rating is assigned, the agency's name, integrity, and credibility are on the line and subject to inspection by the whole investment community" (Wilson [1994]). Over the years, the discipline provided by reputational considerations appears to have been effective, with no major scandals in the ratings industry of which we are aware.³

In addition to putting an agency's reputation at risk, inaccurate ratings might expose the agency to costly legal damages. So far, the threat of legal liability for rating agencies has not yet materialized. Class action suits have been brought against rating agencies following major failures — such as the Washington Public Power Supply System default in 1983 and the Executive Life bankruptcy in 1991 — but the cases were dropped before verdicts were reached.

The Ratings Process and Unsolicited Ratings

Agencies base their ratings on both quantitative and qualitative assessment of the borrowing company's condition and special provisions of the particular security at hand. The process of obtaining a rating can be lengthy, requiring significant time and effort on the part of the debt issuer and its underwriter as well as the agency.

A staff committee at the agency usually votes on a recommendation by a senior analyst after presentation and debate. The rating assigned, often accompanied by explanatory analysis, is first communicated to the issuer and underwriter, and then to the public at large.

The issuer frequently has the opportunity to appeal a rating if it is not satisfied, but in general the ratings process is structured to hear the best case the issuers have to present before the rating is assigned. (More discussion of the information gathering and decision process can be found in Wilson [1994] and Ederington and Yawitz [1987].)

The agencies maintain very different policies about assigning ratings not requested by the issuer. Some agencies will issue ratings only upon request; other agencies will issue unsolicited ratings.

Standard & Poor's rates all taxable securities in the U.S. domestic market registered by the Securities and Exchange Commission (SEC), regardless of whether the rating is requested and paid for by the issuer. Standard & Poor's will not, however, assign unsolicited ratings for structured securities and bonds issued by foreign companies, because it views the non-

public information provided by the issuer to be essential for analyzing these securities.

Moody's shares Standard & Poor's policy of rating all SEC-registered, U.S. corporate securities, but it frequently issues unsolicited ratings on structured securities and foreign bonds as well. In contrast, both Fitch and Duff & Phelps refrain from assigning unsolicited ratings on any security. Moreover, Duff & Phelps will make a rating public only upon the request of its client (Ederington and Yawitz [1987]).

Moody's and Standard & Poor's usually receive fees for ratings they would have issued anyway because companies want the opportunity provided by the formal ratings process to put their best case before the agencies. Moody's unsolicited ratings of issuers of structured securities and foreign bonds are more controversial because such assessments are not part of an overall policy to rate all such securities. Unsolicited ratings in these areas are often substantially lower than the solicited ratings and can affect the yield paid at issuance.

Proponents claim that unsolicited ratings provide a powerful check against rating shopping, the practice of hiring only those agencies that offer favorable ratings. Critics complain that unsolicited ratings are based on incomplete information, because communication with the issuer is limited. Although an agency assigning unsolicited ratings may appear to have an incentive to be unduly conservative so as to reward those firms that do pay for its ratings, this incentive may be offset by the need to maintain a reputation for analytical credibility (Monro-Davis [1994]).

II. THE USE OF RATINGS IN REGULATION

Introduced as guides for unsophisticated investors, credit ratings have acquired several new uses. Many mutual funds and pension funds place limits on the amount of a portfolio that can be invested in non-investment-grade securities. Debt issuers and investors frequently introduce ratings explicitly into the covenants of their financial contracts, and seek guidance from the agencies on the structuring of their financial transactions.

As ratings have gained greater acceptance in the marketplace, regulators of financial markets and institutions have increasingly used ratings to simplify the task of prudential oversight. The reliance on ratings extends to virtually all financial regulators, including the public authorities that oversee banks, thrifts, insurance compa-

EXHIBIT 3 ■ Selected Uses of Ratings in Regulation

Year Adopted	Ratings-Dependent Regulation	Minimum Rating	How Many Ratings?	Regulator/Regulation
1931	Required banks to mark-to-market lower-rated bonds	BBB	2	OCC and Federal Reserve examination rules
1936	Prohibited banks from purchasing "speculative securities"	BBB	Unspecified	OCC, FDIC, and Federal Reserve joint statement
1951	Imposed higher capital requirements on insurers' lower-rated bonds	Various	NA	NAIC mandatory reserve requirements
1975	Imposed higher capital haircuts on broker-dealers' below-investment-grade bonds	BBB	2	SEC amendment to Rule 15c3-1: the uniform net capital rule
1982	Eased disclosure requirements for investment-grade bonds	BBB	1	SEC adoption of Integrated Disclosure System (Release #6383)
1984	Eased issuance of non-agency mortgage-backed securities (MBS)	AA	1	Congressional promulgation of the Secondary Mortgage Market Enhancement Act of 1984
1987	Permitted margin lending against MBS and (later) foreign bonds	AA	1	Federal Reserve Regulation T

^bIf issue is rated by only one NRSRO, its rating is adequate; otherwise, two ratings are required.

nies, securities firms, capital markets, mutual funds, and private pensions.

The early regulatory uses of ratings drew only on the agency distinctions between investment-grade securities or those rated BBB and above, and speculative securities, those rated BB and below. Regulations required that extra capital be held against speculative securities or prohibited such investments altogether.

Although the distinction between investment-grade and speculative securities remains an important one, over time, regulatory capital requirements, disclosure requirements, and investment prohibitions have

increasingly been tied to other letter grades as well. The history of selected uses of ratings by regulators is summarized in Exhibit 3.⁴

Since regulators adopted ratings-dependent rules, they have had to specify which agencies qualify for consideration under their regulations. The SEC currently designates six agencies as "nationally recognized statistical rating organizations" (NRSROs), and the other regulators generally rely on the SEC's designations.

Given the large number of designated agencies (and at least as many agencies have applications pending), regulations must include methods for dealing with

rating disagreements among the agencies. Most regulations simply accept either the highest rating or the second-highest rating, but the insurance regulators conduct independent analyses to resolve disagreements among the agencies. The first approach is arbitrary and perhaps inflationary, while the second approach incurs the cost of establishing in-house analytical capacity.

Traditional Use of Ratings: Distinguishing Investment-Grade From Speculative Securities

On the heels of a sharp decline in credit quality in 1931, the Office of the Comptroller of the Currency ruled that bank holdings of publicly rated bonds had to be rated BBB or better by at least one rating agency if they were to be carried at book value; otherwise the bonds were to be written down to market value, and 50% of the resulting book losses were to be charged against capital. Similar rules were adopted by many state banking departments.

In 1936, the Office of the Comptroller of the Currency and the Federal Reserve went farther, prohibiting banks altogether from holding bonds not rated BBB or above by at least two agencies. The new rules had far-reaching consequences because 891 of 1,975 bonds listed on the New York Stock Exchange were rated below BBB in 1936. Still in force for banks today, these restrictions on investment were extended to thrifts in 1989.

As of the early 1930s, regulators of insurance companies were relying on ratings to help determine the capital to be put aside for securities held. In 1951, the National Association of Insurance Commissioners (NAIC) established a system of internal quality categories in which the top-quality classification corresponded to ratings of BBB and above, effectively establishing uniformity in the definition of "investment-grade" across bank and insurance regulators (West [1973]).⁵

Regulatory rules based on the distinction between investment-grade and speculative securities have since expanded. The SEC has required dealers to hold extra capital against their inventories of speculative or "junk" bonds since 1975. In 1989, Congress passed legislation prohibiting thrifts from investing in junk bonds. In 1993, the Basle Committee on Bank Supervision proposed in its market risk guidelines that internationally active commercial banks dealing in securities should hold extra capital against their non-

investment-grade bond inventories as well. (This passage in the proposal mirrors a similar statement in the European Community's capital adequacy directive governing the activities of security dealers domiciled in the Community.)

The achievement of an investment-grade rating eases the burden of disclosure for the issuer of the securities. In 1982, the SEC started to require less detailed disclosure at issuance for investment-grade securities. In 1993, the SEC adopted Rule 3a-7, which made the investment-grade rating a criterion for easing the public issuance of certain asset-backed securities (see Cantor and Demsetz [1993]).

Embedding the investment-grade distinction in regulations has simplified prudential oversight of financial institutions. Some of these regulations have, as a by-product, adversely affected the availability and cost of funds to below-investment-grade borrowers. West [1973] and Carey et al. [1993] show that spreads rose for borrowers rated BB following the adoption of regulations affecting bank and insurance company investments in below-investment-grade securities.

The Emergence of New Cutoff Ratings

Regulators are increasingly using ratings other than BBB as thresholds in their rules. Each new regulatory use appears to have encouraged other regulators to expand their reliance on ratings. Some of these new rules have greatly influenced the development of capital markets.

In 1984, to promote the development of a mortgage-backed securities market without the support of government-related agencies (Government National Mortgage Association, Federal National Mortgage Association, and Federal Home Loan Mortgage Corporation), Congress passed the Secondary Mortgage Market Enhancement Act (SMMEA). This act eased issuance and enhanced the marketability of mortgage-backed securities rated AAA or AA. In particular, it allows these securities to be marketed up to six months in advance of the delivery of their underlying collateral and exempts them from most states' blue sky laws.

In addition to essentially creating the non-agency mortgage-backed securities market, SMMEA established a new regulatory cutoff rating. The higher AA rating was chosen because mortgage-backed securities with full or partial government backing — the reference securities to which the new securities are compared — were virtually all rated AAA or AA at the time.

A few years later, the Federal Reserve Board, which had previously refrained from expanding its use of ratings beyond the basic investment-grade requirements for bank portfolio investments, also began to incorporate an AA cutoff in certain of its prudential rules affecting bank supervision. In recognition of the expanded role given to ratings by the Congress, the Board began to use AA as a cutoff in rules for determining the eligibility of mortgage-related securities (1987) and foreign bonds (1989) as collateral for margin lending.⁶

The single-A rating has also served as a cutoff. The Labor Department, in its role as overseer of the private pension industry, adopted a regulation in 1988 permitting pension fund investments in asset-backed securities rated single-A or better (Baron and Murch [1993]). The A rating gained further regulatory importance in 1990 when the NAIC adopted new capital rules that apply the least burdensome capital charge to bonds with the NAIC quality designation corresponding to a public rating of A or above.

Short-term ratings too have been important tools of recent regulation. In 1991, the SEC adopted amendments to Rule 2a-7 of the Investment Company Act of 1940 that impose ratings-based restrictions on money market mutual fund investments.⁷ Following the adoption of these amendments, mutual fund holdings of lower-quality paper fell to zero, and the total amount of lower-quality paper outstanding declined sharply (Crabbe and Post [1992]).

Some regulations have gone beyond specific cutoff levels by incorporating schedules of multiple rating levels and corresponding restrictions and charges. As part of its 1990 reform of rating procedures, the NAIC increased the number of its quality categories from four to six, and applied different regulatory restrictions to each category. Four years later, the Federal Financial Institutions Examination Council [1994] joined bank and thrift regulators, including the Federal Reserve, in a proposal to adjust capital charges on depository institutions' holdings of structured securities on the basis of credit ratings.

The Designation of NRSROs

Under most current ratings-dependent regulations in the United States, ratings matter only if they are issued by an NRSRO. The SEC first applied the NRSRO designations to agencies in 1975 in referring to agencies whose credit ratings could be used to

determine net capital requirements for broker-dealers. Subsequently, the term was taken up by regulators other than the SEC and even by the private investment community.

When the phrase NRSRO was first used, the SEC was referring to the three agencies that had a national presence at that time, Moody's, Standard & Poor's, and Fitch. But as the public bond market and the rating industry grew over time, other agencies have sought NRSRO designation from the SEC.

In 1982, Duff & Phelps received designation, followed by IBCA and Thomson BankWatch in 1991 and 1992, respectively. The designation of the latter two has been limited to their ratings for banks and financial institutions only. In 1983, the SEC granted NRSRO status to McCarthy, Crisanti & Maffei, but the company's credit rating franchise was acquired by Duff & Phelps in 1991. At least six foreign rating agencies currently have applications outstanding with the SEC for designation as NRSROs.

At present, the SEC's procedures and conditions for designating agencies as NRSROs are not very explicit. If a rating agency requests NRSRO status from the SEC, the SEC's staff will undertake an investigation, analyzing data supplied by the rating agency about its history, ownership, employees, financial resources, policies, and internal procedures. The principal test applied by the SEC to any agency seeking NRSRO status is that the agency be "nationally recognized by the predominant users of ratings in the United States as an issuer of credible and reliable ratings" (SEC [1994a]).

In effect, the SEC requires that the market already place substantial weight on the judgment of a rating agency. Market acceptance is determined by polling on an informal basis. By giving the market a role in selecting NRSROs, the SEC intends to weed out agencies that have not already established a reputation for accurate ratings.

Nonetheless, the informality of the process and the opaqueness of the acceptance criteria raise serious problems. The requirement that an agency be widely used by major investors before it can be designated as an NRSRO clearly favors incumbents. Given the growing importance of NRSRO status, new entrants in the ratings business who lack this status may find it increasingly difficult to attract a wide following in the investment community. These concerns may become more acute as the SEC considers applications from foreign rating agencies.

At present, the SEC does not require NRSROs to have uniform rating standards. In particular, the Commission has no explicit rule that "equivalent" letter grades must correspond to similar expected default rates. Nonetheless, regulations generally refer directly to NRSRO rating levels without allowances for differences across agencies.⁸

Unless the way in which regulations use ratings is changed, all NRSRO ratings of a certain level ought to correspond to the same level of credit risk. To achieve such consistency, the SEC may have to develop additional acceptance criteria and ongoing monitoring capacity.

In recognition of these concerns, the SEC has published a "concept release" that invites rating agencies, corporations, and investors to comment on "the role of ratings in federal securities laws and the need to establish formal procedures for designating and monitoring the activities of NRSROs" (SEC [1994]).

Resolving Disagreements Among the Rating Agencies

Most ratings-dependent regulations require only that a bond issue carry a single NRSRO's rating, but issuers in the United States commonly obtain at least two ratings on publicly issued securities. Since both Moody's and Standard & Poor's rate virtually all public corporate bond issues, a dual rating is fairly automatic. As a consequence, differences of opinion across the rating agencies inevitably arise. Regulators have had to find a way to resolve these differences because most of their rules key off specific letter grades. Their approaches to the problem take two forms — explicit rules and independent analysis.

The most common approach is to adopt an explicit rule, recognizing either the highest or the second-highest rating, regardless of the number or level of the other ratings. The second-highest rating rule attempts to strike a balance between a conservative policy (eliminating the highest rating) and a liberal policy (not necessarily using the lowest rating).

When the ratings industry was dominated by Moody's and Standard & Poor's, this rule was effectively conservative, because the lower of two ratings was also the lowest rating. As the number of NRSROs has increased, and issuers have begun to obtain three, four, or more ratings, the policy is potentially more liberal. Although regulators could conceivably adopt a more conservative rule (such as the lowest rating), in areas

such as structured finance where Moody's and Standard & Poor's do not attempt to rate every issue, issuers could respond by dropping agencies that assign the lower ratings.

The second approach, used by the NAIC, resolves differences of opinion among the rating agencies through independent analysis. The NAIC's Securities Valuation Office (SVO) assigns each bond held by an insurance company to one of six quality categories, each with a different implication for mandatory reserves. The six quality categories are meant to correspond to different NRSRO public ratings. (Category 1 corresponds to AAA, AA, and A; 2 to BBB; 3 to BB; 4 to B; and 5 or 6 to CCC, C, or D ratings, depending on the rating agency.) SVO staff are free to assign a rating that differs from the bond's public credit rating, however, as long as their judgment implies a downgrade from the corresponding public credit rating.

In practice, the SVO concentrates its resources on 1) determining a quality category for unrated private placement securities, and 2) resolving differences of opinion among the agencies, where the SVO may choose either the higher or lower rating (NAIC [1994]). At the cost of establishing the capacity to undertake independent analysis, the NAIC has developed a discretionary use of ratings that calls for judgment in the interpretation of split ratings and permits certain ratings to be discounted if they are viewed as too high.

III. HISTORICAL RELIABILITY OF RATINGS

Many of the current uses of ratings presume rating agency accuracy in measurement of both *relative* and *absolute* risks of corporate bond defaults. To be meaningful, ratings must, at a minimum, provide a reasonable rank-ordering of relative credit risks. At the same time, however, ratings ought to provide a reliable guide to absolute credit risk. In other words, the ratings levels corresponding to regulatory cutoffs should have a fairly stable relationship to default probabilities over time.

Our review of the corporate bond defaults data assembled by Moody's and Standard & Poor's suggests that the agencies do a reasonable job in assessing relative credit risks; lower-rated bonds do in fact tend to default more frequently than higher-rated bonds. Agency ratings have been a less reliable guide, however, to absolute credit risks; default probabilities associated with their specific letter ratings have drifted over time.

Our review is limited to the Moody's and

Standard & Poor's ratings because only these agencies have a long history of rating a large number of corporate issues. We present data primarily from Moody's, because it has published more historical data than Standard & Poor's. By and large, however, we believe that the patterns observed in Moody's ratings are also present in Standard & Poor's ratings, and we provide some support for this view in the text.

The analysis is limited to corporate bond ratings and excludes commercial paper ratings, municipal bond ratings, or asset-backed bonds. In these other markets, a study of rating reliability is not possible either because defaults have been too rare, the data are too hard to obtain, or the history of the market is too short.

Measuring Relative Credit Risks

Some very simple tests suggest that the rating industry measures relative credit risks with reasonable accuracy. The capital markets seem to validate the agencies' judgments by pricing lower-rated bonds at higher average yields. Moreover, both average short-term and long-term default rates are correlated in a sensible way with credit ratings. This evidence implies that ratings provide a useful rank-ordering of credit risks.

For U.S. corporate bonds, market yields are generally closely related to their credit ratings. Exhibit 4 reports the average yield spreads between corporate bonds and U.S. Treasuries by rating category for issues rated by Standard & Poor's between 1973 and 1987. Each letter grade decline corresponds to a distinct increase in average yield spreads.

The pattern of increasing yields as the rating cat-

egory is lowered is extremely robust, and holds without exception across all years of the sample (Altman [1989]). While this correlation may seem unsurprising, and perhaps a weak test of ratings reliability, Artus, Garrigues, and Sassenou [1993] put forth evidence that, for the French bond market, a direct relationship between yield and the ratings of the largest French bond rating agency is either weak or non-existent.

This simple association of yields and ratings in the U.S. bond market need not indicate the presence of a causal relationship. Rather, it may simply mean that both the capital markets and the rating agencies basically agree on the factors that measure credit risk.

Although the literature is voluminous (see Ederington and Yawitz [1987]), the evidence is mixed on whether credit ratings contain additional information not already embedded in market yields. Even if ratings do not contain independent information about credit risk, the use of ratings by investors and regulators may make sense if ratings offer an efficient summary of this information.

Measuring ratings performance by contemporaneous market yields, however, does not control for waves of market optimism or pessimism. The accumulation of ex post evidence on bond performance provides a more precise scorecard on ratings. Moody's and Standard & Poor's have made such evidence available in their corporate bond default studies, which calculate historical default rates among classes of rated issuers.

These studies indicate that lower corporate bond ratings have indeed been associated with a higher probability of default. The results of the Moody's study (Moody's Investors Service [1994]) are summarized in Exhibit 5, which reviews the default rates among rated issuers between 1970 and 1993.

The upper left panel presents the one-year default rate for the entire sample of rated bonds. Measured to one-tenth of a percentage point, the one-year default rates are zero for all bonds rated A and above. The one-year default rate rises to two-tenths of a percentage point for BBB issuers, and 1.8 and 8.3% for BB and B-rated issuers, respectively.

The other three panels of Exhibit 5 show how the default probabilities across Moody's rating categories change as the time horizon is lengthened to five, ten, and fifteen years.⁹ While the default probability increases with the time horizon for each rating category, the negative relationship between default probability and rating remains intact. A similar historical default

study (Brand, Kitto, and Bahar [1994]) covering bonds rated by Standard & Poor's between 1981 and 1993 basically confirms the conclusion drawn from the longer-term study by Moody's.

Consistent with the traditional importance of the investment-grade/non-investment-grade distinction, the probability of default rises most dramatically once the investment-grade barrier is breached. In the Moody's study, over a five-year time horizon, the default probability is six times higher for bonds rated BB than for those rated BBB. In contrast, the comparable ratio of default probabilities for B-rated versus BB-rated issues is much lower at 2.2, as is the ratio for

BBB-rated versus A-rated issues at 3.2. The same ratios for the Standard & Poor's study are 4.8 (BB versus BBB), 3.0 (BBB versus A), and 1.9 (B versus BB).

Measuring Absolute Credit Risks

The agencies do not intend their ratings to imply precisely the same default probabilities at every time. In particular, they are reluctant to make ratings changes simply on the basis of cyclical considerations, even though the frequency of defaults within rating categories clearly rises in recessions.¹⁰ But even if cyclical variability in short-term default rates is an inevitable result of a longer-term perspective, long-term default

probabilities at the different ratings levels should exhibit relative stability over frequencies longer than the business cycle. In fact, legislators and financial regulators are presuming such a stability when they embed specific credit rating thresholds into law and regulation.

The reliability of ratings as predictors of absolute credit risks can be evaluated by examining the default rates associated with different ratings over time, particularly if the time horizon is long enough to incorporate both ends of a business cycle. Using Moody's data between 1970 and 1994, Exhibit 6 reviews the progress of five-year cumulative default rates for investment-grade and non-investment-grade bonds.

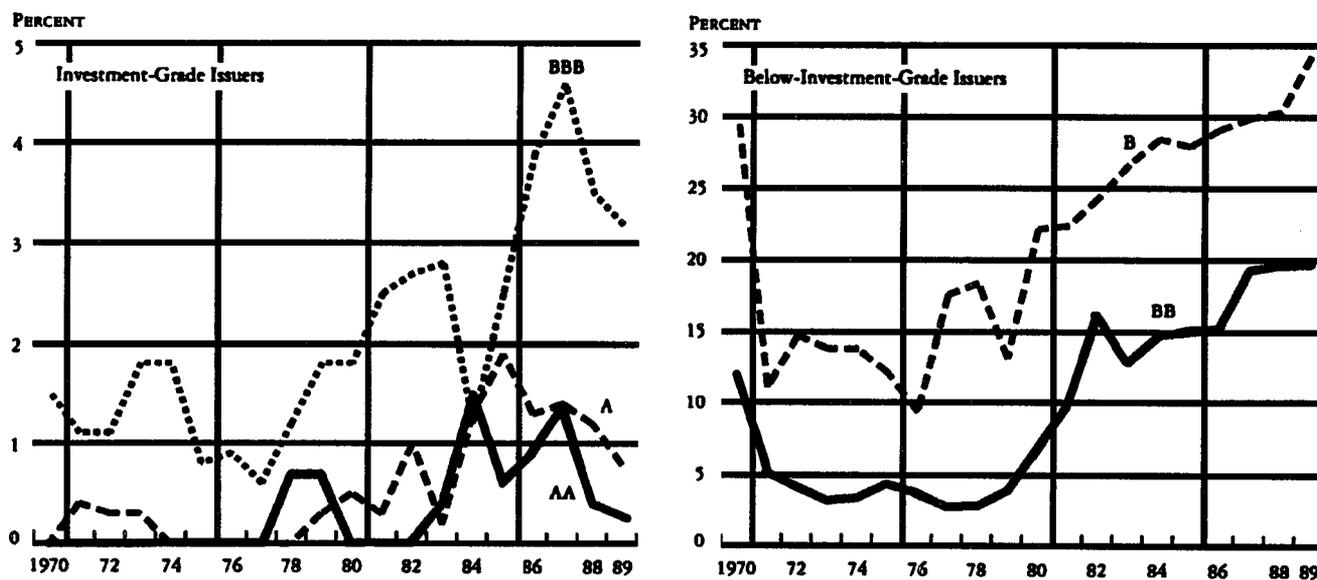

The initial spike in 1970 for non-investment-grade bonds stems from the default that year of Penn Central and twenty-six other railroad companies; default rates decreased dramatically the next year. For cohorts established since January 1971, however, the cumulative default rate within all rating classes BBB and below has increased roughly threefold. The 1971 to 1989 increase is from 0.4% to 0.8% for A-rated bonds, 1.1% to 3.2% for BBB-rated bonds, 5.1% to 19.7% for BB-rated bonds, and 11.1% to 34.3% for B-rated bonds. Five-year default rates now lie well above the highs of 1970.

Although five-year default rates rose during the growth of the junk bond market in the 1980s, deterioration in performance was common to both investment-grade and non-investment-grade samples. The increase in default rates actually began with the 1976, 1977, and 1978 cohorts, whose five-year default rates incorporate defaults that occurred through the end of 1980, 1981, and 1982, respectively. The rising trend in default rates, therefore, was initially related to the early 1980s recession, but continued on through the decade.

In retrospect, the rise in default rates is unsurprising, given the general deterioration in credit ratios within rating classes that began in the mid-1980s. Exhibit 7 shows that the median fixed-charge coverage and leverage ratios of industrial firms with BBB, BB, and B credit ratings from Standard & Poor's generally worsened between 1985 and 1991. These data suggest that a relaxation of credit standards may have occurred, perhaps as a result of the view commonly held in the late 1980s that even healthy corporations should increase leverage.¹¹

Experience since 1970 indicates basically that the correspondence of ratings to default probabilities is subject to substantial change over time.

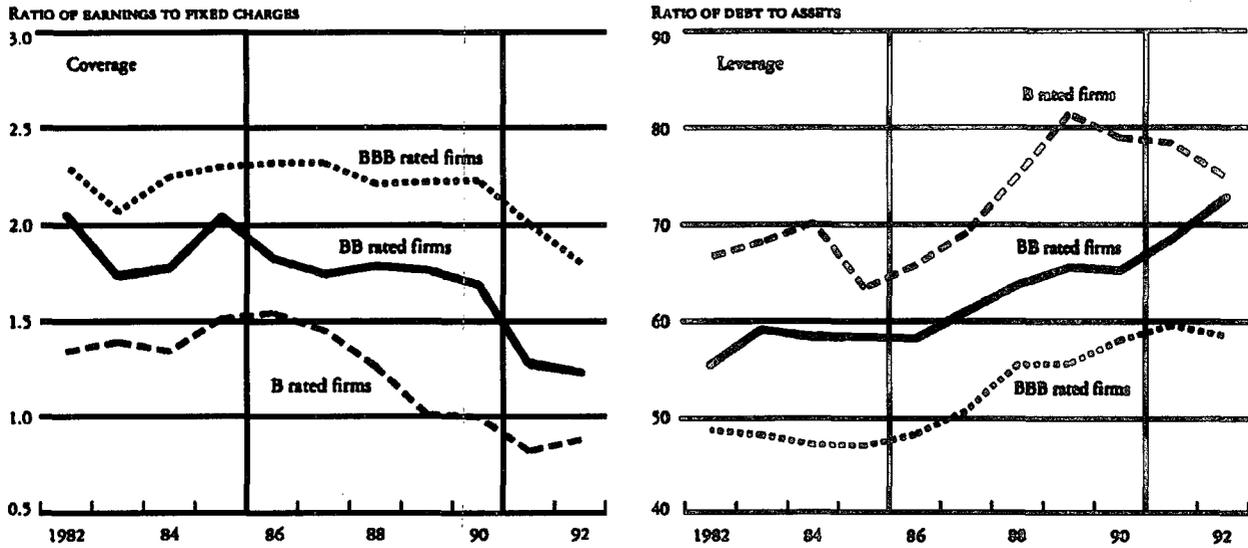

EXHIBIT 6 ■ Trends in Five-Year Default Rates by Credit Rating

Note: The five-year default rate indicates the share of issuers with a given rating at the beginning of the year that defaulted within the following five years.

IV. RATINGS DIFFERENCES ACROSS AGENCIES

Differences among the agencies over specific ratings are common, unavoidable, and even desirable to the extent that disagreements promote better understanding. Nonetheless, these differences can be highly problematic for ratings-based regulation when the ratings of any two NRSROs are substitutable.

Some of the observed differences can be attributed to alternative rating methodologies; others are the results of the element of judgment in the ratings process. Many of the differences, however, may reflect systematic differences among agencies in the acceptable level of risk in any ratings category. We review some of the basic differences in agency methodologies, average ratings, and rank-orderings of credit risks in the context of three important areas of competition within the industry — ratings for new-issue junk bonds, banks, and asset-backed securities.

Ratings Disagreements Stemming From Alternative Methodologies

Although each agency publishes formal definitions of its various letter ratings, these definitions provide

very little insight into the source of agency rating differences. The definitions imply that a different (unquantified) likelihood of default is associated with each letter grade.¹² In addition, rating agencies do not explicitly compare their ratings with those of other agencies.

As a practical matter, however, it appears that market participants have historically viewed the Moody's and Standard & Poor's scales as roughly equivalent, and that the other agencies have attempted to align their scales against those two. But while the relationships among the scales are imprecise, the implicit presumption of ratings-dependent regulation is that the corresponding rating levels of the different NRSROs represent equivalent levels of credit risk and are interchangeable.

Periodically, the rating agencies articulate unique ratings philosophies. For example, although Moody's and Standard & Poor's are primarily concerned with the likelihood of default on interest or principal, Moody's is prepared to give a higher rating to an asset-backed security that is likely to recover most of its principal in the event of default.¹³ In addition, in the area of rating sovereign credit risks, Moody's is more reluctant to assign a higher rating to a country's domestic currency obligations relative to its foreign currency obligations

The Journal of Fixed Income, 1995, 5, 3:10-34. Downloaded from www.ijournals.com by HARVARD UNIVERSITY on 04/08/10. It is illegal to make unauthorized copies of this article, forward to an unauthorized user or to post electronically without Publisher permission.

than is Standard & Poor's (Purcell et al. [1993]).

The other agencies also differ from their counterparts in certain particulars. For example, unlike other agencies, Duff & Phelps sometimes gives higher ratings for the medium-term notes than for the longer-term securities of the same issuers. And IBCA assigns higher ratings to certain non-U.S. banks than do the U.S. agencies, because it attaches more weight to a foreign government's implicit support of the banking system.

Individual agencies often describe the bases for their positions in their documents, but how their methodologies differ from other agencies' generally must be inferred.

Broad Differences Observed in Ratings

Beattie and Searle [1992a] summarize the ratings differences observed in a large sample of long-term credit ratings assigned in 1990 by twelve of the leading international rating agencies and recorded by the *Financial Times* in its quarterly publication, *Credit Ratings International*. Among the 5,284 rating pairs examined for 1,853 rated borrowers, 44% agree precisely, 35% differ by one rating notch, 14% by two notches, and 6% by three or more notches. (A "rating notch" is, for example, the gap between an A and A+ rating.)

The percentage in agreement is somewhat over-

EXHIBIT 8 ■ Senior Debt Ratings of Nine Rating Agencies Compared with Moody's Ratings in 1990

Source: Beattie and Searle [1992a].

stated in the analysis of Beattie and Searle, because they lump all speculative-grade ratings into a single ratings level. The differences across agencies as measured by the frequency of agreement compound two potential sources of disagreement — mean rating scales and rank-orderings.

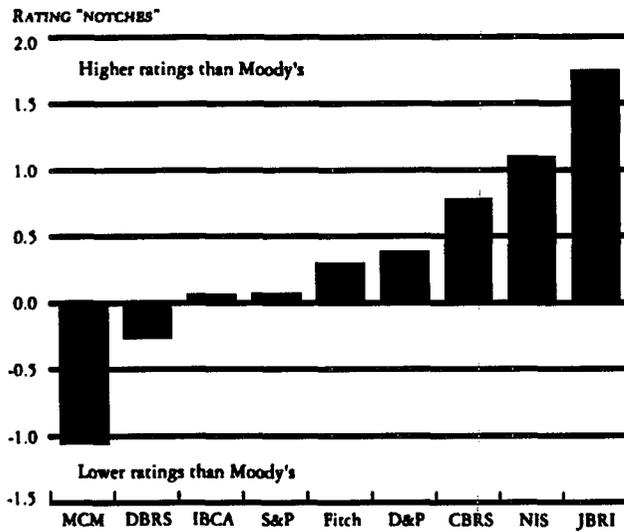

The two largest NRSROs, Moody's and Standard & Poor's, assign very similar average ratings and rank-orderings of credit risks. Of the 1,398 cases in 1990 in which senior debt ratings were assigned by both companies, 64% were assigned the same rating, 16% were rated higher by Moody's, and 20% were rated higher by Standard & Poor's. The average (mean) difference in their ratings (including all those cases where their ratings were the same) was only five-one-hundredths of a notch.¹⁴ Not surprisingly, Moody's and Standard & Poor's ratings are very highly correlated at 0.97, revealing a general consensus regarding rank-ordering of relative risks.¹⁵

This rough equivalence in the rating standards of Moody's and Standard & Poor's does not seem to extend to other rating agencies. Exhibit 8 compares the ratings given by nine agencies with those given by Moody's to the same borrowers. (Moody's ratings are used as the basis of comparison simply because this agency has the most ratings in the data set.) Three measures of ratings differences are presented: the frequency of agreement, the correlation coefficients, and the average ratings differences.

Standard & Poor's agrees most closely with Moody's (64%), while the percentage agreement varies among the rest to a low of 11% for the Japan Credit Rating Agency. Compared with Standard & Poor's ratings, the ratings of the other agencies exhibit larger average absolute ratings differences and less correlation with Moody's ratings.

These differences in ratings reflect not only differences in rank-orderings of credit risks, but, to a large extent, also differences in rating scales. Exhibit 9 shows that most of the agencies rate higher than Moody's, although McCarthy, Crisanti, and Maffei (since merged with Duff & Phelps) rates on average a whole rating notch lower. The two largest American agencies after Moody's and Standard & Poor's, Fitch and Duff & Phelps, each rate about a third of a notch higher than Moody's.¹⁶ The Canadian Bond Rating Service, Nippon Investors Service, and the Japan Credit Rating Agency rate on average 0.78, 1.09, and 1.75 notches higher than Moody's.

EXHIBIT 9 ■ Average Differences in Ratings between Moody's and Other Agencies in 1990

Notes: Rating notches are gaps between ratings. For example, the gap between A+ and A- is two notches. Average differences are calculated using only the ratings of issuers that were rated by both Moody's and the other agency.

Source: Beattie and Searle [1992a].

Ratings For New-Issue Junk Bonds

From the point of view of regulatory practice, a rise in the number of rating agencies increases the likelihood that marginal borrowers will meet minimum ratings thresholds because 1) natural variation in opinion increases the probability of receiving at least one satisfactory rating, and 2) some rating agencies may have higher average rating scales, enabling more borrowers to meet regulatory cutoffs. We can observe the

impact of multiple rating agencies on regulatory definitions of investment-grade securities by documenting agency disagreements in the junk bond market.

As generally defined, any issue is considered "junk" that has at least one rating below the BBB- level from either Moody's or Standard & Poor's. After falling off in the early 1990s, junk bond issues reached a new high of \$57 billion (18.2%) in 1993 (Fridson [1994]).

Of the nearly 700 new U.S. junk issues between 1989 and 1993 listed in First Boston's annual *High-Yield Handbook*, 96% are rated by both Moody's and Standard & Poor's. Junk bond issuers, however, are increasingly seeking third and fourth ratings as well. Duff & Phelps and Fitch, which respectively rated 16% and 4% of all issues in the 1989-1993 period, have significantly increased their rating activity in the past few years (see Exhibit 10).

The junk bond sample reveals more striking differences in agency measurements of absolute and relative credit risks than does the broad sample. Standard & Poor's and Moody's are much more often at odds in the ratings they assign junk bond issuers. If we compare the junk bond ratings in Exhibit 11 with the ratings for the broad sample in Exhibit 8, we find smaller frequencies of agreement and smaller correlation coefficients. The providers of third (and fourth) opinions in this sector, Duff & Phelps and Fitch, also appear to disagree with Moody's with greater regularity and on a greater scale in the junk bond sample.

For the newer rating agencies, many of the observed differences may be related to a difference in their absolute scales in rating credit risks. While Moody's and Standard & Poor's rate about the same on average for jointly rated issues, Duff & Phelps and Fitch ratings are between 1 and 1.5 rating notches higher than Moody's or Standard & Poor's. These differences

EXHIBIT 12 ■ The Decision to Obtain a Third Rating

Notes: The sample consists of 671 junk bond issues brought to market between 1989 and 1993. The issues received the following combinations of ratings from Moody's and Standard & Poor's: 74 rated BBB/BB, 132 rated BB/BB, 79 rated BB/B, 359 rated B/B, and 27 rated B/CCC or CCC/CCC. Each bar in the chart indicates the fraction of the issues that were given a third rating from another agency.

Source: *High-Yield Handbook* 1990-1994.

greatly exceed those reported in Exhibit 8 for the aggregate sample of bond issues. Thus, differences of opinion between the two largest and the smaller agencies appear to be greater for junk bonds than for investment-grade securities.

Given the possibilities for split ratings, the decision to employ a third rating agency is not random. Exhibit 12 relates the frequency with which issuers seek a third rating to the ratings received from Moody's and Standard & Poor's. Issuers are more likely to obtain a third rating if they receive near-investment-grade or mixed (speculative-grade/investment-grade) ratings from Moody's and Standard & Poor's.

In particular, 46% of the firms with one investment-grade rating from the major two agencies obtained a third opinion. Of these thirty-four firms, twenty-nine obtained a second investment-grade rating. Among issuers that received marginally below-investment-grade ratings (BB-ratings) from both Moody's and Standard & Poor's, 26% obtained a third rating. Of these thirty-four firms, sixteen obtained an investment-grade rating.

Our conclusion is that the demand for third ratings increases with the issuer's proximity to investment-grade, and the opportunity to seek third and fourth ratings has enabled a number of firms to achieve investment-grade status under certain regulations.

International Bank Ratings

As capital markets have become increasingly global, international considerations have assumed greater importance in the ratings industry. U.S. rating agencies have been expanding their presence overseas, and non-U.S. rating agencies are proliferating.

Credit ratings are particularly important to banks (through counterparty exposure limits, letters of credit, and non-deposit sources of funds),¹⁷ and a large number of ratings in the industry are cross-border ratings. In addition, the potential designation of certain foreign agencies as NRSROs may have considerable impact on the activities of foreign banks in the United States.

Dominant in many other industry sectors, Moody's and Standard & Poor's are the leading agencies in the rating of banks. Of the 1,018 banks worldwide for which long-term bond ratings were available in January 1994, Moody's and Standard & Poor's rated 64% and 55%, respectively (*Financial Times* [1994]).¹⁸ When the sample is limited to just those 580 rated banks domiciled outside the United States, Moody's and Standard &

EXHIBIT 13 ■ Percentage Market Shares of International Bank Ratings in 1994

Agency	Home Country	All Banks	U.S. Banks	Non-U.S. Banks	Home Country Ratings as a Percentage of Total Ratings of Each Agency

S&P	U.S.	50.3	66.3	35.9	61.9
Thom	U.S.	9.7	16.9	3.4	81.3
IBCA	U.K.	30.0	23.5	35.7	9.2

Sources: *Financial Times* [1994]; Federal Reserve Bank of New York staff estimates.

Poor's still rated 57% and 46%, while IBCA was in third position at 31%. While these three leading agencies rate many banks outside their home countries, most of the other agencies tend to specialize in ratings of banks of their own nationality (see Exhibit 13).

Agencies appear to disagree more in their measurement of credit risks for banks than in their risk measurement for other industries. In Exhibit 14, the bank ratings of nine leading rating agencies generally show lower frequencies of agreement and higher absolute ratings differences relative to Moody's than does the broader ratings sample described in Exhibit 8.¹⁹ The differences are greater for the agencies of some countries than for the agencies of others. In particular, the ratings of Japanese agencies differ much more from those of Moody's than do the ratings of other agencies.

What accounts for the wide disagreement? For the U.S. and Canadian agencies, agreement concerning relative risk declines as we move from the broad ratings sample to the bank sample, as evidenced by lower correlation coefficients. By contrast, for the Japanese agencies, the wider disagreement reflects higher average rating differentials.

National differences in methodology and approach may also help explain the variation in international bank ratings. For example, the accounting for

non-performing loans and reserves is not standardized by country, and opinions vary widely regarding the extent to which particular governments lend implicit support to specific banks in the banking system.

Indeed, judgments regarding controversial issues are related to some degree to the nationality of rating agencies. When raters are from the same country, agreement about the relative ranking of issuers, as measured by the coefficient of correlation, tends to be higher than when they are not.²⁰

Are observed bank ratings consistent with earlier research concluding that agencies judge issuers from their own country more leniently (Beattie and Searle [1992b])? When the ratings of all banks evaluated by both home-country and foreign agencies are aggregated, the average home rating exceeds the average foreign rating by one-half of a rating notch.

Results differ greatly depending on the nationality of the bank (Exhibit 15).

While U.S. and Canadian banks receive lower home

EXHIBIT 14 ■ International Bank Ratings of Nine Rating Agencies Compared with Moody's Ratings in 1994

EXHIBIT 15 ■ Average Senior Debt Ratings Assigned to Banks By Home and Foreign Agencies

Notes: Observations are limited to banks with both home-country and foreign-country senior debt ratings. Sample sizes for the five bank groups (from left to right) are 100, 17, 35, 18, and 170.

Sources: *Financial Times* [1994]; Federal Reserve Bank of New York staff estimates.

ratings than foreign ratings, Japanese and U.K. banks receive higher home ratings.

At least in this sample, observed differences between home and foreign ratings reflect the relative toughness of each country's agencies rather than a more general home-country bias. Whether the rated bank is from the same country or not does not bear on the differences between the ratings of non-U.S. agencies and Moody's.

International ratings differences are of particular importance at the present time because the SEC is reviewing numerous applications for NRSRO designation from agencies of foreign countries. Differences among the agencies of different countries and the tendency of many agencies to focus on the rating of banks from their home countries imply that if NRSRO status were to be granted to the two Canadian and three Japanese rating agencies, the number of Canadian and Japanese banks reaching regulatory cutoff ratings would increase considerably.

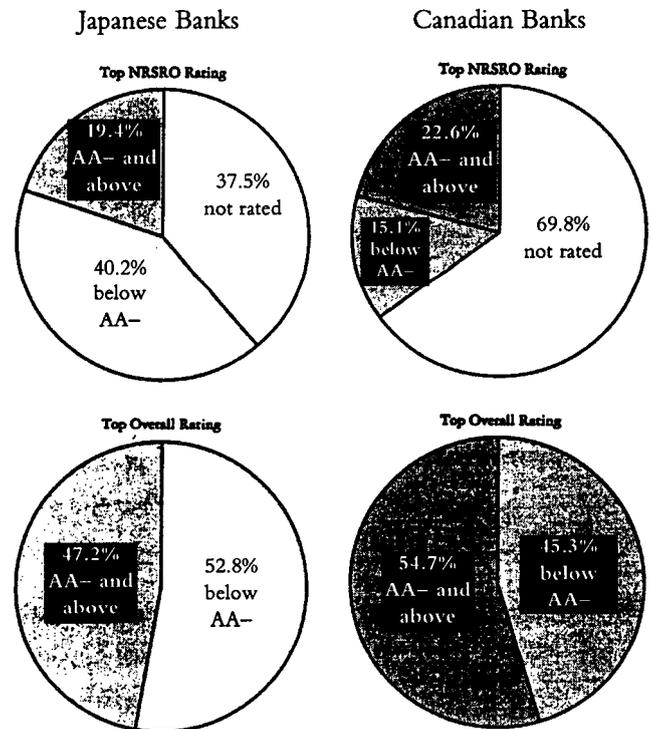

As Exhibit 16 shows, of the fifty-three Canadian

banks with senior debt ratings listed in the *Financial Times Credit Ratings International* [1994], the share receiving an NRSRO credit rating of at least AA- would rise from 23% to 55%. Similarly, of the seventy-four Japanese banks with senior debt ratings listed in the same publication, the share receiving an NRSRO rating of at least AA- would rise from 20% to 48%.

Ratings For Mortgage- and Asset-Backed Securities

Competition among the rating agencies is particularly marked in the rating of mortgage-backed and asset-backed securities (MBS and ABS).²¹ Issuers often seek ratings from just one or two companies, and as we see below, Fitch and Duff & Phelps have

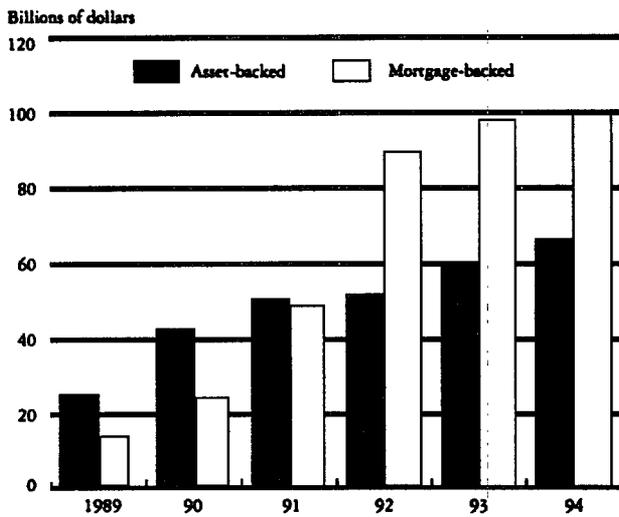

EXHIBIT 16 ■ Implications of Expanding the Number of Nationally Recognized Statistical Rating Organizations (NRSROs)

Notes: The Japanese sample and the Canadian sample consist of seventy-two and fifty-three banks, respectively. Top NRSRO rating is the highest long-term rating of those assigned by Duff, Fitch, IBCA, Moody's, S&P, and Thomson. Top overall rating is the highest long-term rating of those assigned by the NRSROs and the following non-NRSROs: CBRS, DBRS, JBRI, JCRA, and NIS.

increased market share.

Banks and securities firms generally consult directly with the rating agencies to find out how MBS and ABS can be structured to obtain high credit ratings. The agencies analyze the asset pools to be securitized to determine the adequacy of the credit support underlying each tranche of structured transactions.

Agency disagreements normally center on the criteria that establish the amount of credit enhancement required for a specific rating. These differences of opinion are not normally evident in the ratings per se because issuers structure their securities to obtain the desired ratings from the agencies they hire. (Moody's occasionally assigns unsolicited ratings that indicate its disagreement with the higher ratings assigned by other agencies.) Market observers have expressed concern that competitive pressures have led agencies to compete on ratings criteria, potentially undermining the reliability of the ratings.²²

Industry analysts normally distinguish between two broad categories of MBS, those backed by government agencies such as the Federal National Mortgage Association, and private-label issues that securitize jumbo mortgages, commercial mortgages, and various

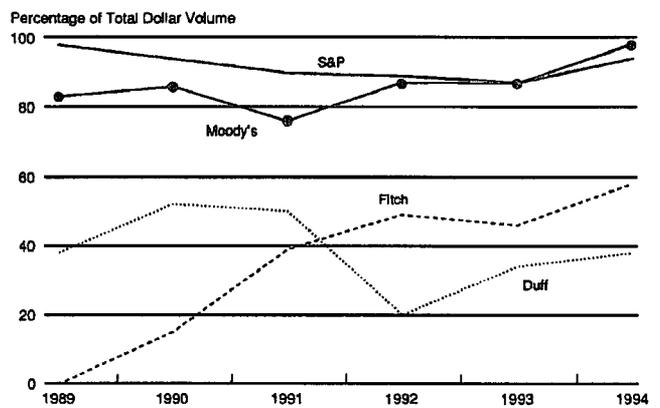

other so-called non-conforming first mortgages that the government agencies do not securitize. The ABS market securitizes shorter-duration asset pools such as credit card receivables, auto loans, and home equity loans. The MBS and ABS markets have grown very rapidly since 1989 (Exhibit 17).

Rating agency market shares for MBS and ABS ratings have shifted considerably over time. In the mid-1980s, Standard & Poor's was the undisputed leader in MBS and ABS ratings. In the late 1980s, Moody's caught up considerably, and Duff & Phelps made significant inroads in the ABS market. Since then, Fitch has made great strides in market share, actually leading the market for MBS in 1994, while the other agencies' shares have fluctuated.

Exhibits 18 and 19 summarize the available data on these two markets since 1989. (Because more than one agency can rate each security, the sum of the shares exceeds 100%.)

Unlike the corporate bond market, the MBS and ABS markets are limited almost entirely to highly rated issues, typically either AA or AAA for MBS, and A or AAA for ABS. The need for high ratings appears to arise from the advantages regulations confer on highly rated (particularly MBS) issues and from investors' concerns about the quality of the collateral as well as

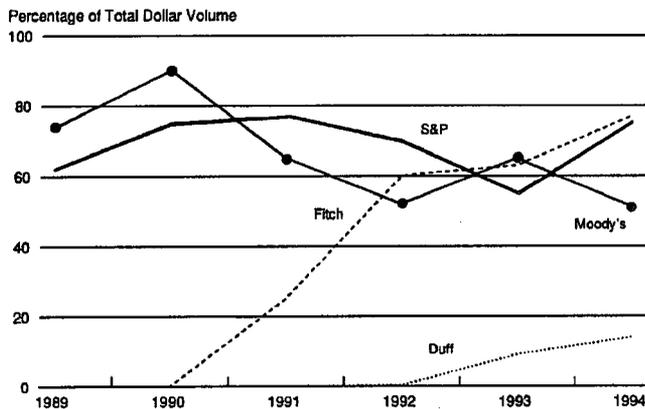

EXHIBIT 18 ■ Rating Agency Market Shares of Asset-Backed Securities Issuance

their unfamiliarity with the complicated structures of the securities.

The relatively small share of MBS and ABS that are rated less than A consists largely of "B" tranches that are subordinate to much larger, highly rated senior tranches. The subordinated tranches tend to be privately placed and are often rated by just a single agency or carry no rating at all.

MBS and ABS structures typically include credit protection so that the securities are less risky than the underlying asset pools. The forms of the credit enhancements vary widely, and include bank letters of credit, bond insurance company guarantees, subordinated interests, cash collateral accounts, and reinvestment of the excess cash flow generated by the asset pools themselves. Since all enhancements are costly, issuers prefer structures that achieve a given rating with the smallest enhancements, and choose rating agencies with the most lenient credit enhancement requirements, provided the agencies' ratings carry sufficient weight in the capital market.

In principle, securities with lower credit enhancements can be discounted by the market. In practice, however, the market has trusted agencies to be prudent in the determination of credit support requirements and has not required higher yields from issuers

that have switched to agencies with lower enhancement requirements (Bruskin [1994]).

The evolution of credit rating standards and the emergence of market competition have been particularly dramatic in the case of private-label mortgage-backed securities. Until the mid-1980s, Standard & Poor's was the only agency rating these securities, and its required credit enhancements for reaching target ratings represented the industry standard.

In 1986, Moody's entered the market with criteria that were slightly different. While its standards are stricter than those of Standard & Poor's in some areas, Moody's set lower enhancement requirements for certain types of mortgage pools (shorter-term, negative amortization, and convertible adjustable-rate mortgages) and subsequently gained market share in those areas.

In 1987 and 1988, Moody's issued some unsolicited ratings (in areas where its standards are stricter than those of Standard & Poor's) and caused yields to rise on these securities. In response, some issuers changed their MBS structures and hired Moody's. By 1989, Moody's share of the MBS business exceeded that of Standard & Poor's.

In 1990, Fitch began rating mortgage-backed securities using a model of required credit enhancement that bases its worst case scenarios on the Texas recession of the 1980s. This approach resulted in required enhancements below those of Standard & Poor's (lower by as much as 50% for certain balloon payment mortgages), whose model extrapolates from the mortgage default experience of the Great Depression. Duff & Phelps followed suit with a framework similar to Fitch's in 1992.

Standard & Poor's, which once had a monopoly, saw its market share slide to 55% in 1993 as many issuers who had at one time employed only Standard & Poor's, then later used Standard & Poor's together with Moody's, had switched to a pairing of Fitch and Moody's.

In December 1993, Standard & Poor's came out with revised criteria for credit enhancements that implied a 30% reduction on average across a variety of mortgage pool types. Explanations for the changes followed the next month (Standard & Poor's [1994]). Some of the revisions are in those areas in which the agency had been losing market share, including shorter-term mortgages. Rival rating agencies claimed that the move represented a competitive attempt to win back market share.

In the first four months of 1994, then, Standard

& Poor's regained market share, largely at Moody's expense. It is difficult to tell at this point whether the shift reflects issuers moving from one agency to another, or merely a growth in issuance by firms that use Standard & Poor's ratings (see Schultz [1994] and *Inside Mortgage Securities* [1994a, 1994b]).

Clearly, MBS credit enhancement levels have declined over the history of the market. Analysts and agencies note that this in part reflects a progression along the learning curve; more information has become available over time about the performance of such securities, reducing the degree of uncertainty.

Skeptics remark that competitive pressures can lead to increased pressures to review standards. Whether or not agencies compete on criteria, it does appear that the incentive to innovate in structured finance ratings tends to favor lower enhancement levels.

V. CONCLUSION

Regulators, like investors, value the cost savings achieved through the use of ratings in the credit evaluation process. As a result, they have come to employ a variety of specific letter ratings as thresholds for determining capital charges and defining investment prohibitions.

Although the agencies make no such assurances, the current use of ratings in regulation assumes a stable relationship between ratings and default probabilities. The historical record suggests otherwise. Although ratings usefully order credit risks at any particular time, specific letter ratings corresponded to higher default risks in the 1980s than in the 1970s.

The increasing number of agencies also poses problems for the existing structure of ratings-based regulation. Some agencies appear to have different absolute scales, rating bonds higher or lower on average than other agencies. And even normal variation in opinion across agencies with the same basic scales confounds the application of existing regulations. These problems multiply as the number of agencies and the differences of opinion among them increase.

The impact of multiple rating agencies and ratings differences is apparent in the case studies of junk bond, bank debt, and mortgage-backed securities ratings. For junk bonds, the availability of third opinions enables many borrowers to climb out of the speculative-grade zone into investment-grade territory. In the area of bank debt ratings, differences of opinion are par-

ticularly great between agencies of different countries and imply that the designation of more foreign agencies as NRSROs will allow more foreign banks to achieve higher ratings. Regarding private-label mortgage-backed securities, intensifying competition among the four major agencies has been associated with downward revisions of required enhancement levels.

The Securities and Exchange Commission [1994a, 1994b] is reconsidering its procedures for designating nationally recognized agencies (NRSROs), the role of ratings in regulation, and the degree of public oversight and mandatory ratings disclosure. Questions for which comments have been solicited include:

- What are the proper objective criteria to consider when determining NRSRO status?
- Is it appropriate for NRSROs to charge issuers for ratings, and in particular, to vary the charge with the size of the transaction?
- Would further regulatory oversight of NRSROs be appropriate, and what type of oversight would that be?
- Should issuers be required to disclose activities such as rating shopping — soliciting preliminary indications from numerous rating agencies in order to identify the agency that will provide the highest rating?

The SEC's questions all raise the possibility of additional oversight or disclosure of NRSRO activity and the ratings process. Such measures could conceivably address some of the issues we have raised, by improving the intertemporal stability of default rates within ratings category and by reducing differences among the officially designated agencies. Of course, any changes in policy would entail complex trade-offs; specific proposals and their implications will surely be explored in future research.

The SEC has also invited comment on whether it should continue to employ an NRSRO concept. Although dropping the designation of NRSROs would be a radical measure, it might encourage regulators to revise their current use of ratings and to adjust for ratings differences across time and agency.

Ratings can and do play an important and valuable role in the functioning and oversight of financial markets. But regulators and investors alike should be critical users, and regularly review their application of ratings to the decisions they make.

ENDNOTES

¹Government policy has helped to avert conflicts of interest. The Federal Reserve Board discouraged a proposed acquisition of Duff & Phelps by Security Pacific Bank in 1984. The Board ruled that if the merger took place, Duff & Phelps would be prohibited from issuing public ratings because Security Pacific would effectively be rating its own borrowers (Ederington and Yawitz [1987]).

²See the descriptions of agencies' ratings methodology in the *Financial Times* [1994, pp. 25-79]. Comparisons across the agencies' rating scales are more difficult in the lowest part of the range near default, where the agencies carry different numbers of ratings (Dale and Thomas [1991]).

³For a more critical view, see Stein [1992].

⁴Dale and Thomas [1991] and Baron and Murch [1993] provide comprehensive discussions of the current use of ratings by regulators in the United States and abroad. Harold [1938] provides a detailed account of the earliest uses of ratings in the United States.

⁵Under this system, insurance companies were allowed to request that specific BB-rated bonds be treated the same as those more highly rated bonds in the top quality category. This practice, which became common over time, was halted by reforms adopted by the NAIC in 1990.

⁶In analyzing the margin rules for mortgage-related securities, Federal Reserve Board staff reasoned thus:

The question of using bond ratings by a recognized service as a criterion for margin eligibility was discussed when the initial definition of "OTC margin bond" was under consideration. The National Association of Securities Dealers proposed a rating standard at that time and most securities dealers endorsed its use for non-listed bonds in comment letter, but the Board declined to adopt such a requirement. Since that time, however, the SEC has used these evaluations of third parties as a means of categorizing some debt securities; regulatory examiners use them to determine investment grade; and the United States Congress has mandated their use in the statutory definition under consideration. Staff believes that developments subsequent to the 1978 decision warrant a departure from the Board's earlier decision (Board of Governors [1987]).

⁷These rules key off the agencies' short-term ratings, limiting money funds from holding more than 5% of their assets in paper rated A2 by Standard & Poor's (P2 by Moody's) or more than 1% in any paper of a single A2/P2 issuer. Issuers with these weaker short-term ratings typically have long-term bond ratings that are still rated well above the investment-grade cutoff.

⁸When voicing its concerns over the 1991 amend-

ments to Rule 2a-7, the Securities Industry Association noted that "rating categories were not designed as regulatory tools and NRSROs may change their criteria from time to time as they deem appropriate. Further, when determining ratings, rating agencies neither use uniform criteria nor weigh the same criteria equally" (Grafton [1992]).

⁹The Moody's study calculates the default rate formally as a *weighted-average cumulative default rate*, which is the complement of the product of weighted-average marginal survival rates. For details concerning rate calculations, see the Appendix in Moody's Investors Service [1994].

¹⁰As reported by Fons [1991], most of the cyclical variation in the aggregate default rate on corporate bonds cannot be explained by cyclical variations in Moody's ratings on bond outstandings. Moreover, since yield spreads between high- and low-rated bonds tend to rise during recessions, market pricing is consistent with a perceived rise in the default probabilities of lower-rated issues relative to those of higher-rated issues during recessions. Alternatively, the rise in spreads in recessions may merely reflect a concurrent rise in the market's aversion to default risk or other supply and demand factors.

¹¹Wigmore [1990] documents a much more severe difference between the 1986-1988 average credit ratios and the 1983-1985 ratios than is suggested by the Standard & Poor's data presented in Exhibits 16 and 17 for bonds rated BB or B. According to Wigmore, the Standard & Poor's data understate the decline in credit quality because a greater proportion of the junk bonds issued in the later period were issued by companies in conjunction with leveraging events (mergers, acquisitions, and leveraged buyouts); these current credit ratios were much weaker than the historical credit ratios included in the Standard & Poor's data. In contrast, Fridson [1991] argues that much of the apparent deterioration in credit ratios and increases in default rates for B-rated issues in the late 1980s can be explained by an increase in the proportion of issuers rated B- as opposed to B or B+.

¹²Moody's and Standard & Poor's now provide ex post analyses of corporate bond defaults by rating categories. Variations in default probabilities for Moody's and Standard & Poor's can, therefore, be inferred from these studies.

¹³Standard & Poor's is generally less willing to base ratings on expected recoveries, even though it has always made such distinctions, as have all the other agencies, for different classes of debt issued by the same firm. Whenever a firm defaults on its subordinated debt, its senior debt is almost always drawn into default as well. Nevertheless, agencies regularly award higher ratings to the senior debt because its expected recovery rate is higher.

¹⁴Other authors with data sets also note a rough equivalence between Moody's and Standard & Poor's ratings (Perry [1985], Ederington [1986], Ederington and Yawitz [1987]). Moreover, Billingsley, Lamy, Marr, and Thompson

[1985] show that the market views Moody's and Standard & Poor's ratings as equivalent because the yields on bond issues with split ratings do not depend on which agency assigns the higher rating.

¹⁵The Pearson product-moment correlation coefficient, which can range from -1.00 to a maximum value of 1.00, measures the extent to which rank-orderings agree while removing any confounding effects of differences in average rating scores and differences in units of measurement.

¹⁶These agencies acknowledge that their ratings are higher than Moody's and Standard & Poor's on average; they attribute some of the ratings difference to sample selection bias. They argue that ratings from Fitch or Duff & Phelps are sought only when there is a strong expectation of improving upon Moody's and Standard & Poor's ratings. When Fitch or Duff & Phelps might, in fact, rate lower, their ratings are not purchased.

¹⁷For example, U.S. issuers of commercial paper and long-term securities often obtain bank letters of credit in order to achieve targeted credit ratings, but the attractiveness of such backing depends greatly on the credit rating of the bank issuing the letter of credit. When Standard & Poor's put three Japanese banks on its CreditWatch list (with negative implications) in March 1994, the bond issues of 144 U.S. bond issuers and 46 U.S. commercial paper issues that were backed by letters of credit from these banks were also put on CreditWatch.

¹⁸The ratings of the French rating agency S&P-ADEF, a joint venture founded in 1990 by Standard & Poor's and *Agence d'Evaluation Financière*, are counted as Standard & Poor's ratings for the purposes of calculating global market share. The *Financial Times* may underestimate the market share of some rating agencies that publish ratings of only selected bank holding company subsidiaries.

¹⁹The one consistent exception is IBCA, which shows more agreement with Moody's on these measures for banks than does the wider sample. This finding may reflect IBCA's initial specialization in the rating of financial institutions and the limitation of its NRSRO designation to that area.

²⁰The mean of the Pearson product-moment correlation for ratings of agencies from the same country is 0.858, compared with a mean of 0.775 for the correlation coefficients for the ratings of agencies from different countries. The standard errors of measurement for the two coefficients are 0.018 and 0.054, respectively.

²¹We follow industry practice in using "asset-backed securities" (ABS) in the more narrow sense that excludes mortgage-backed securities (MBS).

²²See Bruskin [1988, 1994], Schultz [1994], and *Inside Mortgage Securities* [1994a, 1994b]. Our discussion of the evolution of ratings criteria for MBS draws heavily from these sources.
